INSULIN RESISTANCE TESTS

Test	Result
Fasting insulin	Lower than 5 mU/L is good; higher than 12 mU/L makes insulin resistance very likely ¹
Fasting blood glucose	Should be less than 85 mg/dL (4.7 mmol/L) ²
Fasting triglycerides (fat in the blood)	Ideally less than 100 mg/dL (1.13 mmol/L); Over 150 mg/dL (1.7 mmol/L) makes insulin resistance very likely (Note: if you are African-American you can have very low fasting triglycerides but still have insulin resistance.) ³
HDL (so-called "good cholesterol")	Higher than 40 mg/dL (1.04 mmol/L) in men is good Higher than 50 mg/dL (1.3 mmol/L) in women is good ⁴
Triglycerides/HDL ratio (Divide your triglycerides by your HDL. It doesn't matter whether your test results are in mg/dL or mmol/L, so long as both the triglycerides and the HDL are measured using the same units.	The closer to 1.0 the better, but here are the high risk cutoff values: Non-African-American: Below 3.0 is good African-American: Below 2.0 is good ⁵
Waist index (Divide your waist measurement in centimeters by the number that applies to your ethnicity and gender listed in the box to the right.)	Non-Asian men: waist circumference (cm) ÷ 94 South Asian/Chinese men: waist circumference (cm) ÷ 90 Japanese men: waist circumference (cm) ÷ 85 Non-Japanese women: waist circumference (cm) ÷ 80 (Not a reliable indicator in Japanese women) Below 1.15 is good ^{6,7,8}
HsCRP (highly-sensitive C-reactive protein) (this is a marker of inflammation)	Lower than 1 mg/dL (0.055 mmol/L) is good ⁹
Uric acid	Standard cutoffs for insulin resistance are: Lower than 6 mg/dL in men is good Lower than 5 mg/dL in women is good ¹⁰ A <u>recent study</u> suggests values may need to be even lower to reduce risk for mental health disorders: Women < 4 mg/dL is good Men < 5.35 mg/dL is good ¹¹

lest	Result
HOMA-IR	Fasting insulin (mU/L) X Fasting glucose (mg/dL) ÷ 405 OR
	Fasting insulin (mU/L) x Fasting glucose (mmol/L) ÷ 22.5
	Cutoff values in <u>scientific studies</u> vary between 1.7 and 3.9 but most experts agree that a HOMA-IR of 1.0 is excellent. ¹² Higher is worse, with levels of 3.0 or more indicating significant insulin resistance.
Postprandial glucose test A simple way to get a sense of your carbohydrate tolerance/ insulin resistance at home is to test your own blood glucose one hour after eating a meal that contains carbohydrates.	If blood glucose rises to 140 mg/dL (7.77 mmol/L) or higher, you likely have insulin resistance (and should avoid foods that cause your glucose to spike into that danger zone). ^{14, 15}

Kraft Insulin Assay

Toot

The most sensitive, accurate and illuminating insulin resistance test available to consumers is the Kraft Insulin Assay. This test is more complicated and harder to access than other tests and is probably not necessary for most people, but <u>it is available in the U.S.</u> You can learn all about the Kraft test in <u>this video</u> by Ivor Cummins, Dr. Jeffry Gerber, and Dr. Kraft himself.

Triglyceride Glucose Index

If your triglycerides and glucose are in mg/dL, multiply your fasting blood glucose by your fasting triglycerides and divide the result by 2. Then take the natural log* of this number.

In
$$\left(\frac{\text{Fasting Blood Glucose (mg/dL) } X \text{ Fasting Triglycerides (mg/dL)}}{2}\right)$$

If your triglycerides and glucose are in mmol/L, multiply your fasting blood glucose by your fasting triglycerides and then multiply the result by 162. Then take the natural log of this number.

Men with values over 8.82 and women with values over 8.73 are most likely to be insulin resistant and have double the chance of developing type 2 diabetes in the future.¹³

*Note: the natural log function (In) is found on a standard scientific calculator. Most smartphone calculators include this function in landscape view.
